# ML For Beginners The Basics of Python (Day 1) Supervised Learning Regression and Demand Forecasting (Day 2) Classification and Fairness (Day 3) Unsupervised Learning Clustering (Day 4) Text Mining (Day 5)

Today

Google Colab

Introduction to Python

```
Python - The Basics

x = 34 - 23  # A comment.
y = "Hello"  # Another one.
z = 3.45
if z == 3.45 or y == "Hello":
    x = x + 1
    y = y + " World"  # String concat.
print (x)
print (y)
```

### **Python – The Basics**

- · Indentation matters to code meaning
- First assignment to a variable creates it
- Assignment is = and comparison is ==
- For numbers + \* / % are as expected
- Logical operators are words (and, or, not) not symbols
- The basic printing command is print

Utrecht University

13

# Python – Data Types

Integers (default for numbers)

x = 3

**Floats** 

x = 3.456

Strings

Can use "" (double quotation) or " (single quotation) to specify strings

"abc" == 'abc'

Unmatched can occur within the string: "matt's"

Utrecht University

### **Python – The Basics**

- Use a newline to end a line of code
  - Use \ when must go to next line prematurely
- indentations mark blocks of code
- Colons start of a new block in many constructs, e.g. function definitions, conditional clauses, loops
- Start comments with #, rest of line is ignored
- Use triple double quotation for comments over multiple lines

```
''' This comment goes
```

# **Python – The Basics**

You can assign to multiple names at the same time

$$x, y = 2, 3$$

This makes it easy to swap values

$$x$$
,  $y = y$ ,  $x$ 

Assignments can be chained

$$a = b = x = 2$$

	Utrecht University
--	--------------------

### **Python – The Basics**

Accessing a variable before it's been properly created raises an error print (w)

-----

NameError Traceback (most recent call last) <ipython-input-35-ad11782dc618> in <module> ----> 1 print (w) NameError: name 'w' is not defined

Instead

$$w = 3$$
 print(w)

# Python – Tuples, Lists, Strings, and Arrays

- Tuple: t = ('john', 32, [CMSC])
- Strings: s = "John Smith" or s = 'John Smith'
- List: 1 = [1, 2, 'john', ('up', 'down')]
- Arrays: requires importing the numpy library
  - import numpy as np
  - $_1d = np.array([1, 2, 3])$
  - \_2d = np.array ([[1, 2, 3], [4, 5, 6]])

18

# Python – Matrices and Sets

- A matrix is 2-dimensional array
  - import numpy as np
  - mat1 = np.matrix ([[1, 2, 3], [4, 5, 6]])
  - mat2 = np.matrix ('1, 2, 3; 4, 5, 6')
- A set is list with no repetitions of the elements
  - set1 = set([1, 1, 2, 3, 3, 4])
  - The contents of set1 will be {1, 2, 3, 4}

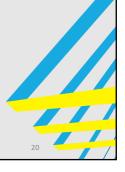

Utrecht University

10

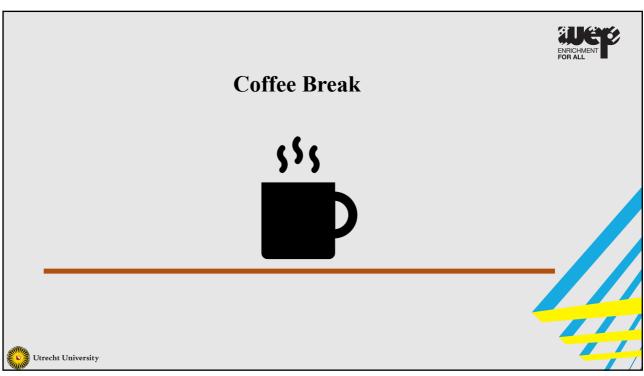

# **Python – Computing Statistical Quantities**

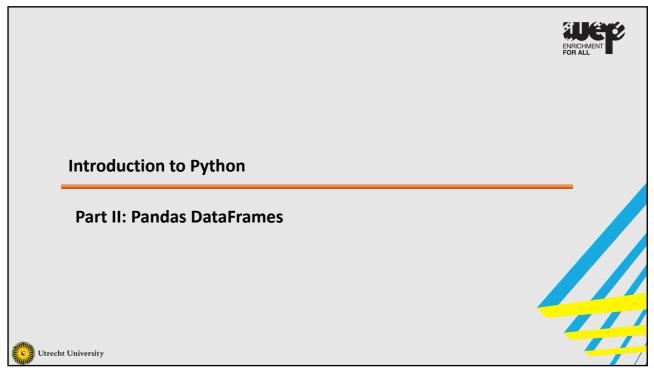

- Mean value
  - import numpy as np
  - np.mean([1, 2, 3, 4, 5, 6]) # OR
  - np.array([1, 2, 3, 4, 5, 6]).mean()
- Standard deviation
  - np.std([1, 2, 3, 4, 5, 6]) # OR
  - np.array([1, 2, 3, 4, 5, 6]).std()

Utrecht University

#### **Pandas Dataframes**

- The most popular way to handle data tables in Python is using Pandas dataframes
- DataFrame: a rectangular table of data and contains an ordered collection of columns, each of which can be a different value type (numeric, string, boolean, etc.)
- Has columns and rows indexes
- Columns are made up of pandas series

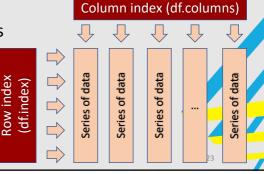

2002

Nevada

Nevada 2003

2.9

3.2

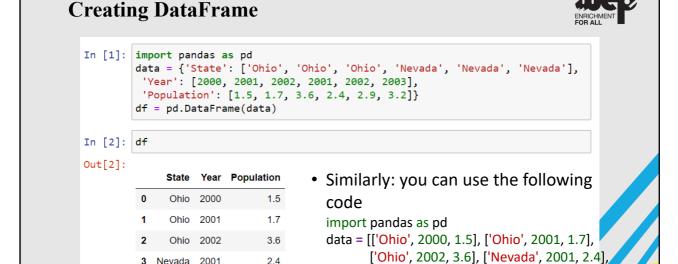

['Nevada', 2002, 2.9], ['Nevada', 2003, 3.2]]

cols = ['State', 'Year', 'Population']

df = pd.DataFrame(data, columns = cols)

23

Utrecht University

Utrecht University

#### **Load DataFrame from CSV Files**

• The simplest way is:

```
df = pd.read_csv('file.csv')  # often works
```

• More options can be added when loading a csv file into a dataframe

```
df = pd.read_csv('movies.csv', header=0,
    index_col=0, quotechar='"', sep=",",
    na_values = ['na', '-', '.', ''])
```

- More options can be found in Pandas documentation
- Remeber to import the pandas library as pd

25

#### **Load DataFrame from EXCEL Files**

• Each Excel sheet in a Pandas dataframe

```
workbook = pd.ExcelFile('movies.xlsx')

df = workbook.parse(workbook.sheet_names[0])
```

- The parse() method takes many arguments like read\_csv().
- Refer to the pandas documentation

26

# **Working with Dataframes**

- Consider the movies dataset extracted from imdb dataset
- Start by reading the csv file

• Extract sub-table of the dataframe

```
df.info()  # index & data types
n = 4
dfh = df.head(n)  # get first n rows
dft = df.tail(n)  # get last n rows
dfs = df.describe()  # summary stats cols
top_left_corner_df = df.iloc[:5, :5]
```

27

27

# **Extracting Data from Dataframes**

Extarct row number 0

```
row1 = df.iloc[0,:] #You may ignore adding the :
row1 = df.iloc[0]
```

• Extract the column with the names of directors

```
df.director_name # OR
df["director_name"]
```

28

### **Extracting Data from Dataframes (Cont.)**

Extract set of rows

```
Rows_set1 = df.iloc[5:10, ] # Extracts rows 5,6,7,8, and 9
Rows_set2 = df.iloc[[5,6,8,10], ] # Extracts rows 5,6,8, and 10
```

• Extract set of columns

```
cols_set1 = df[df.columns[5:10]][:]  # Extracts columns 5,6,7,8, and 9
cols_set2 = df[df.columns[[5,7,9]]][:]  # Extracts columns 5,7, and 9
col_set3 = df[['actor_3_facebook_likes', 'actor_1_facebook_likes', 'content_rating']]
```

 Note that: df.columns is a vector that contains the attributes' names

29

# **Extracting Data from Dataframes (Cont.)**

Extract set of rows with a condition

You can do the same thing using iloc

```
df.iloc[(df['content_rating'] == 'PG-13').values, [1, 3]]
```

• Note that: iloc requires numerical values for the indexes

30

# Profiling the Dataframes • Display number of columns print(len(df.columns)) • Display number of rows print(len(df)) # OR print(len(df[df.columns[0]]) • Find the number of non-null values in each column (attribute) df.count()

Profiling the Dataframes

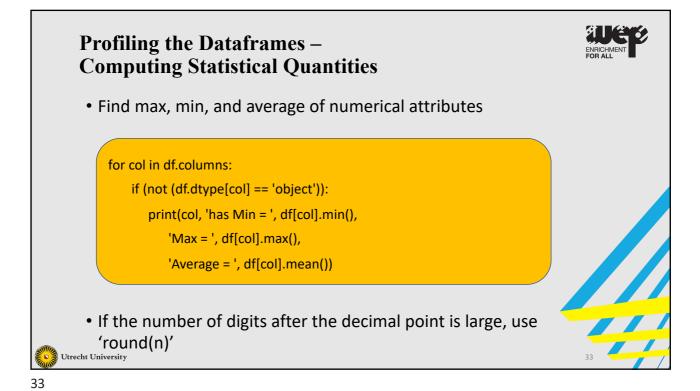

• Display number of distinct values in an attribute

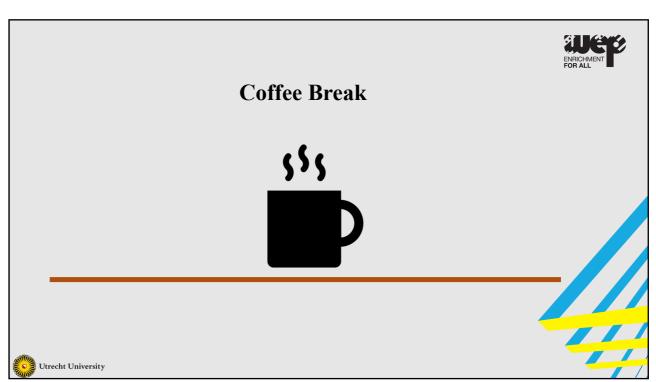

for col in df.columns:
 print(col, ' has (', len(df[col].unique()), ') unique values')

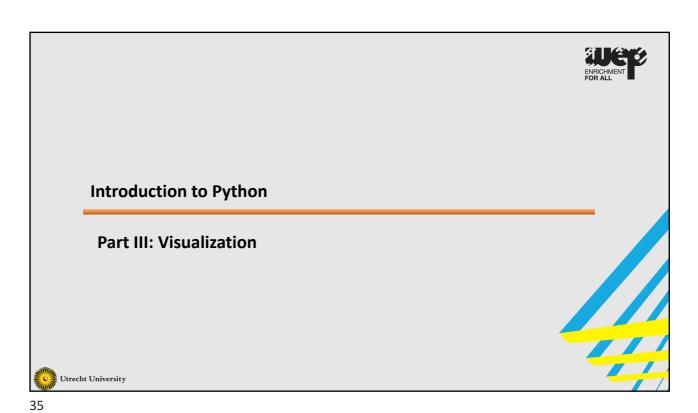

• Display the data type of each attribute

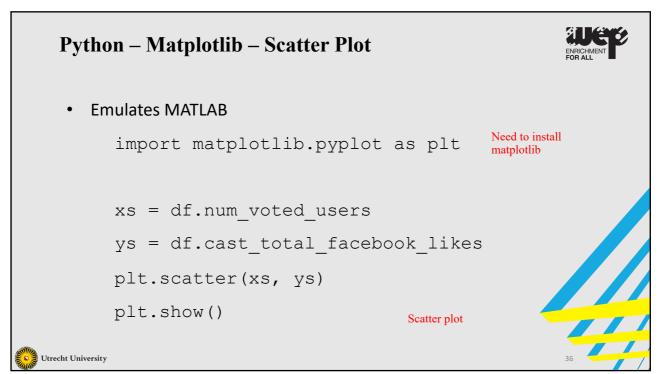

dataTypeSeries = df.dtypes
for col\_idx in range(len(df.columns)):
 print(df.columns[col\_idx], 'has type (', dataTypeSeries[col\_idx], ')')

# Python - Matplotlib - Line Plot import matplotlib.pyplot as plt

```
ENRICHMENT FOR ALL
```

```
xs = [1,2,3,4,5]
ys = [x**2 for x in xs]

plt.plot(xs, ys)  # OR
plt.plot(xs, ys, linewidth = 5, color = 'r')
plt.show()
```

27

Utrecht University

# Python - Matplotlib - Bar Plot

import matplotlib.pyplot as plt

```
xs = [1, 2, 3, 4, 5]
ys = [3, 2, 4, 2, 8]
colors = ['b', 'k', 'r', 'g', 'c']
plt.bar(xs, ys, color = colors, edgecolor = "black")
plt.savefig('barPlot.pdf', bbox_inches = 'tight')
plt.show()
```

Utrecht University

# Python – Matplotlib – Pie Chart

```
import matplotlib.pyplot as plt

xs = ['AMCS', 'CS', 'EE', 'B', 'CBRC']
ys = [10, 20, 50, 15, 5]
plt.pie(ys, labels = xs, autopct='%1.1f%%')
plt.savefig('pieChart.pdf', bbox_inches = 'tight')
plt.show()
```

# Python - Exercise

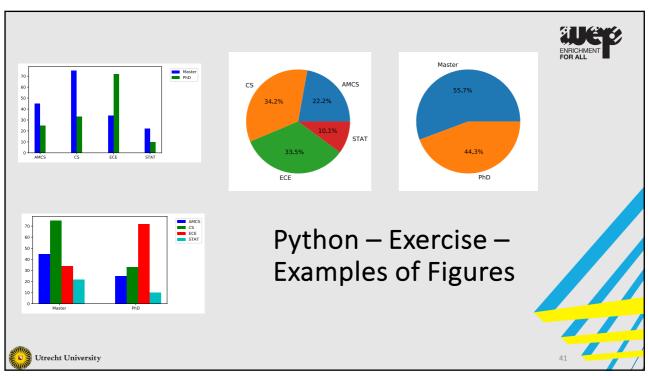

Consider the following data for the number of students in different programs

program	AMCS	cs	ECE	STAT
Master	45	75	34	22
PhD	25	33	72	10

• Draw the data as bar plot and pie chart

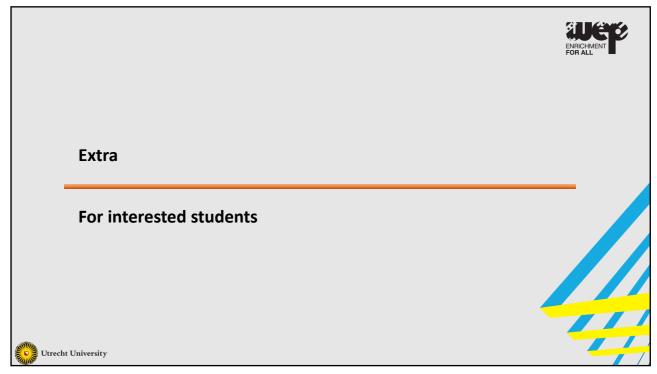

40

#### **Set Operations on Dataframes**

Assume the following dataframes

• The concat function concatenates the dataframes allowing repetition

```
union_df = pd.concat([dd1, dd2])  # concatenate row-wise (default)
union_df = pd.concat([dd1, dd2], axis = 1)  # concatenate column-wise
```

Utrecht University

45

#### Join Operation on Dataframes

• The merge function joins dataframes on selected attribute

```
df_merge_col = pd.merge(dd1, dd2, on='id')
```

• If the joining attribute has different names in both dataframes

```
df_merge_col = pd.merge(dd1, dd2, left_on='att_dd1', right_on = 'att_dd2')
```

Utrecht University
